

## CLAIMS

What is claimed is:

- 1        1.        A measurement-while-drilling (MWD) apparatus conveyed within a borehole for  
2                determining electrical properties of a formation surrounding said borehole, said  
3                MWD device comprising:
  - 4                (a)        a rotatable drill collar;
  - 5                (b)        at least one stabilizer coupled to said collar and rotating at the same speed  
6                        as said drill collar;
  - 7                (c)        a hardfacing on outer face of said at least one stabilizer to maintain a  
8                        desired standoff from the borehole wall;
  - 9                (d)        at least one transmitter on the at least one stabilizer for conveying of at  
10                        least one RF signal into said formation; and
  - 11                (e)        at least one receiver on the at least one stabilizer, said at least one  
12                        transmitter and said at least one receiver, for obtaining a resistivity image  
13                        of the earth formation from a signal received at the at least one receiver  
14                        resulting from interaction of the at least one RF signal with said  
15                        formation..
- 1        2.        The method of claim 1 wherein the at least one transmitter and the at least one  
2                receiver comprise a plurality of transmitter-receiver distances.

- 1        3.        The apparatus of claim 1, wherein said at least one stabilizer is extendable.
- 1        4.        The apparatus of claim 1, wherein said at least one transmitter further comprises  
2                two spaced-apart collimated transmitting antennae.
- 1        5.        The apparatus of claim 4, wherein said at least one receiver further comprises two  
2                spaced-apart collimated receiving antennae evenly positioned between said at  
3                least two transmitting antennae.
- 1        6.        The apparatus of claim 1, wherein said at least one transmitter and said at least  
2                one receiver are operated substantially within a frequency range of 10 MHz to 2  
3                GHz
- 1        7.        The apparatus of claim 1 further comprising an analog to digital (A/D) converter  
2                for undersampling of said at least one received signal.
- 1        8.        The apparatus of claim 1, further comprising at least one of: i) an axial  
2                accelerometer, or ii) a second resistivity sensor at a different axial position, for  
3                determining a rate of penetration of said drill collar.
- 1        9.        The apparatus of claim 1, further comprising at least one transmitter and at least  
2                one receiver on an additional stabilizer.

- 1        10.     The apparatus of claim 1, wherein said at least one receiver and said at least one  
2               transmitter are disposed within at least one cavity along the outer face of said at  
3               least one stabilizer, said at least one cavity having a rectangular slot.
- 1        11.     The apparatus of claim 10, wherein a long side of said rectangular slot is parallel  
2               to the direction of a magnetic dipole moment of one of: i) the transmitter, and, ii)  
3               the receiver disposed within said cavity.
- 1        12.     The apparatus of claim 11, wherein a magnetic dipole moment of the at least one  
2               transmitter and the at least one receiver are aligned parallel to a longitudinal axis  
3               of the drill collar.
- 1        13.     The apparatus of claim 11, wherein a magnetic dipole moment of the at least one  
2               transmitter and the at least one receiver are aligned perpendicular to a  
3               longitudinal axis of the drill collar.
- 1        14.     The apparatus of claim 11, wherein a magnetic dipole moment of the at least one  
2               transmitter is aligned substantially orthogonal to a dipole moment of the at least  
3               one receiver
- 1        15.     A method of determining electrical properties of a formation surrounding a  
2               borehole, comprising:  
3               (a)     conveying a logging tool having a rotatable drill collar into a borehole;

- 4 (b) using at least one transmitter positioned on at least one stabilizer coupled  
5 to said rotatable drill collar to inject at least one RF signal into said  
6 formation;
- 7 (c) using at least one receiver positioned on said at least one stabilizer for  
8 making a measurement of at least one of (I) a phase, and, (II) an  
9 attenuation, of said RF signal upon propagation through said formation,;  
10 and
- 11 (d) using a hardfacing on outer face of said extendable stabilizer to maintain a  
12 desired standoff from the borehole wall.

1 16. The method of claim 15 wherein said at least one transmitter and said at least one  
2 receiver define a plurality of transmitter-receiver spacings.

1 17. The method of claim 15, wherein said at least one stabilizer is extendable.

1 18. The method of claim 15, wherein using said at least one transmitter further  
2 comprises using two spaced-apart collimated transmitting antennae.

1 19. The method of claim 15, wherein said at least one receiver further comprises two  
2 spaced-apart collimated receiving antennae evenly positioned between said at  
3 least two transmitting antennae.

- 1        20.     The method of claim 15, wherein using said at least one transmitter and said at  
2                least one receiver further comprises operating said at least one transmitter and  
3                said at least one receiver substantially within a frequency range of 10 MHz to 2  
4                GHz.
- 1        21.     The apparatus of claim 15, further comprising determining a rate of penetration of  
2                said drill collar using one of: i) an axial accelerometer, or ii) a second resistivity  
3                sensor at a different axial position.
- 1        22.     The method of claim 15, further comprising at least one transmitter and at least  
2                one receiver on an additional stabilizer.
- 1        23.     The method of claim 15, wherein said at least one receiver and said at least one  
2                transmitter are disposed within at least one cavity along the outer face of said at  
3                least one stabilizer, said at least one cavity having a rectangular slot.
- 1        24.     The method of claim 23, wherein a long side of said rectangular slot is parallel to  
2                the direction of a magnetic dipole moment of one of: i) the transmitter, and, ii) the  
3                receiver disposed within said cavity.
- 1        25.     The method of claim 23, wherein a magnetic dipole moment of the at least one  
2                transmitter and the at least one receiver are aligned parallel to a longitudinal axis  
3                of the drill collar.

1       26.     The method of claim 23, wherein a magnetic dipole moment of the at least one  
2             transmitter and the at least one receiver are aligned substantially parallel to each  
3             other

1       27.     The method of claim 23, wherein a magnetic dipole moment of the at least one  
2             transmitter is aligned substantially orthogonal to a dipole moment of the at least  
3             one receiver.

1       28.     The method of claim 15 further comprising undersampling said propagated RF  
2             signal.

1       29.     The method of claim 15 further comprising determining from said at least one  
2             measurement at least one of (i) a resistivity of said formation, (ii) a resistivity of a  
3             connate formation fluid, (iii) a dielectric constant of a dry rock matrix, and, (iv) a  
4             water filled porosity of the formation.

1       30.     The method of claim 15 further comprising repeating step (c) at a plurality of  
2             angular positions of said logging tool and at a plurality of depths of said logging  
3             tool in the borehole, providing a plurality of measurements.

1       31.     The method of claim 30 further comprising determining from said plurality of  
2             measurements a resistivity image of a wall of said borehole.

- 1        32.    The method of claim 30 further comprising using a downhole processor for  
2                   determining from said plurality of measurements an apparent dip of a bed  
3                   boundary.
- 1        33.    The method of claim 30 further comprising using a downhole orientation sensor  
2                   for measuring said angular positions.
- 1        34.    The method of claim 30 further comprising determining said plurality of depths at  
2                   least in part from downhole accelerometer measurements.
- 1        35.    The method of claim 32 further comprising determining said plurality of depths at  
2                   least in part from downhole measurements.
- 1        36.    The method of claim 35 further comprising telemetering said apparent dip and  
2                   said downhole depth measurements to an uphole location.
- 1        37.    The method of claim 36 further comprising:  
2                   (i)        comparing said telemetered downhole depth measurements with depth  
3                   measurements made at a surface location, and  
4                   (ii)       using a processor for correcting said apparent dip based on said  
                 comparison.
